```

The screenshot shows the Red Hat OpenShift Container Platform web console. The left sidebar contains navigation links: Administrator, Home, Overview, Projects, Search, API Explorer, Events, Operators (selected), OperatorHub (selected), Installed Operators, and Workloads. The main content area is titled 'OperatorHub' and displays a list of operators. The 'All Items' tab is active, showing a search bar and a list of operators. Two operators are visible: '[DEPRECATED] Hazelcast Operator' provided by Hazelcast, Inc., and 'Advanced Cluster Management for Kubernetes' provided by Red Hat. The Hazelcast operator is marked as deprecated and has a 'Community' tag. The Red Hat operator is the 'Advanced Cluster Management for Kubernetes' operator, which provides advanced provisioning and management of OpenShift and its components.

## OperatorHub

Discover Operators from the Kubernetes community and Red Hat partners, curated by Red Hat. You can purchase provide optional add-ons and shared services to your developers. After installation, the Operator capabilities will

Red Hat OpenShift Pipelines is a cloud-native continuous integration and delivery (CI/CD) solution for building pipelines using [Tekton](#). Tekton is a flexible Kubernetes-native open-source CI/CD framework, which enables automating deployments across multiple platforms (Kubernetes, serverless, VMs, etc) by abstracting away the underlying details.

## Features

- Standard CI/CD pipelines definition
- Build images with Kubernetes tools such as S2I, Buildah, Buildpacks, Kaniko, etc
- Deploy applications to multiple platforms such as Kubernetes, serverless and VMs
- Easy to extend and integrate with existing tools
- Scale pipelines on-demand
- Portable across any Kubernetes platform
- Designed for microservices and decentralized team
- Integrated with OpenShift Developer Console

## Installation

*Red Hat OpenShift Pipelines Operator* gets installed into a single namespace (openshift-operators) which would then install *Red Hat OpenShift Pipelines* into the openshift-pipelines namespace. *Red Hat OpenShift Pipelines* is however cluster-wide and can run pipelines created in any namespace.

## Components

- Tekton Pipelines: v0.24.3
- Tekton Triggers: v0.14.2
- ClusterTasks based on Tekton Catalog 0.24

## Getting Started

### Install Operator

Install your Operator by subscribing to one of the update channels to keep the Operator up to date. The strategy determines either manual or automatic updates.

#### Update channel \* ⓘ

- ☐ preview
- ☒ stable

#### Installation mode \*

- ☒ All namespaces on the cluster (default)  
Operator will be available in all Namespaces.
- ☐ A specific namespace on the cluster  
This mode is not supported by this Operator

#### Installed Namespace \*

openshift-operators

#### Update approval \* ⓘ

- ☒ Automatic
- ☐ Manual

Install

Cancel

Red Hat OpenShift Pipelines  
provided by Red Hat

#### Provided APIs

##### TC Tekton Config

Represents an installation of latest version of Tekton components, TektonPipeline, TektonTrigger and TektonAddon

##### TP Tekton Pipelines

Represents an installation of latest version of Tekton Pipelines

##### TT Tekton Triggers

Represents an installation of latest version of Tekton Triggers

##### TA Tekton Addons

Represents an installation of latest version of Addons (exclusively ClusterTasks, consoleyamlsamples, consolecleardownloads and consolequickstarts)

Description

YAML

**YAML Linter**

The following task is used to provide static analysis on YAML files mounted using **yamllint** (YAML linter).

**Installing the Task**

```
1 kubectl apply -f https://api.hub.tekton.dev/v1/resource/tekton/task/yaml-lint/0.1/raw
```

**Parameters**

- args:** The extra params along with the file path needs to be provided as the part of **args**. (Default: **["--help"]**)

**Workspaces**

registry.redhat.io/openshift-gitops-1/gitops-rhel8-operator@sha256:67cd9f0b3c969fdala62a732be1f7ca356c32c4d4913eefe689674408cabb8c

Red Hat OpenShift GitOps is a declarative continuous delivery platform based on [Argo CD](#). It enables teams to adopt GitOps principles for managing cluster configurations and automating secure and repeatable application delivery across hybrid multi-cluster Kubernetes environments. Following GitOps and infrastructure as code principles, you can store the configuration of clusters and applications in Git repositories and use Git workflows to roll them out to the target clusters.

## Features

- Automated install and upgrades of Argo CD
- Manual and automated configuration sync from Git repositories to target OpenShift and Kubernetes clusters
- Support for the Helm and Kustomize templating tools
- Configuration drift detection and visualization on live clusters
- Audit trails of rollouts to the clusters
- Monitoring and logging integration with OpenShift
- Automated GitOps bootstrapping using Tekton and Argo CD with [GitOps Application Manager CLI](#)

## Components

- Argo CD v2.1.8
- GitOps Application Manager CLI ([download](#))

## How to Install

After installing the OpenShift GitOps operator, an instance of Argo CD is installed in the `openshift-gitops` namespace which has sufficient privileges for managing cluster configurations. You can create additional Argo CD instances using the `ArgoCD` custom resource within the desired namespaces.

```
apiVersion: argoproj.io/v1alpha1
kind: ArgoCD
metadata:
  name: argocd
spec:
  server:
```

## Install Operator

Install your Operator by subscribing to one of the update channels to keep the Operator up to date. The strategy determines either manual or automatic updates.

OpenShift Platform Plus  
Red Hat Advanced Cluster  
Management for  
Kubernetes

Red Hat Advanced Cluster Management for Kubernetes provides the multicloud hub, a central management console for managing multiple Kubernetes-based clusters across data centers, public clouds, and private clouds. You can use the hub to create Red Hat OpenShift Container Platform clusters on selected providers, or import existing Kubernetes-based clusters. After the clusters are managed, you can set compliance requirements to ensure that the clusters maintain the specified security requirements. You can also deploy business applications across your clusters.

Red Hat Advanced Cluster Management for Kubernetes also provides the following operators:

- Multicloud subscriptions: An operator that provides application management capabilities including subscribing to resources from a channel and deploying those resources on MCH-managed Kubernetes clusters based on placement rules.
- Hive for Red Hat OpenShift: An operator that provides APIs for provisioning and performing initial configuration of OpenShift clusters. These operators are used by the multicloud hub to provide its provisioning and application-management capabilities.

## How to Install

Use of this Red Hat product requires a licensing and subscription agreement.

Install the Red Hat Advanced Cluster Management for Kubernetes operator by following instructions presented when you click the **Install** button. After installing the operator, create an instance of the **MulticloudHub** resource to install the hub. Note that if you will be using the hub to manage non-OpenShift 4.x clusters, you will need to create a Kubernetes **Secret** resource containing your OpenShift pull secret and specify this **Secret** in the **MulticloudHub** resource, as described in the install documentation.

You can find additional installation guidance in the [install documentation](#).

## Install Operator

Install your Operator by subscribing to one of the update channels to keep the Operator up to date. The strategy determines either manual or automatic updates.

## Credentials

The screenshot displays the Red Hat OpenShift Advanced Cluster Management interface. The left sidebar contains navigation links: Home, Overview, Search, Infrastructure (selected), Applications, Governance, and Credentials. Under 'Infrastructure', 'Clusters' is highlighted. The main panel shows the 'Clusters' overview with tabs for Managed clusters, Cluster sets, Cluster pools, and Discovered clusters. A prominent card titled 'Create Cluster on Premise with a cloud like experience' describes the solution for creating clusters at scale. Below this, a table lists existing clusters. The first entry is 'local-cluster', which is in a 'Ready' state, managed by 'aws Amazon Web Services' using 'OpenShift 4.9.38'. It includes a link to view details ('IS more') and indicates 5 nodes.

Name	Status	Infrastructure provider	Distribution version	Labels	Nodes
<input type="checkbox"/> local-cluster	Ready	aws Amazon Web Services	OpenShift 4.9.38	velero.io/exclude-from-backup=true IS more	5

## Edit labels

Labels help you organize and select resources. Adding labels allows you to query for objects by using the labels. Selecting labels during policy and application creation allows you to distribute your resources to different clusters that share common labels.

## Manage resource assignments

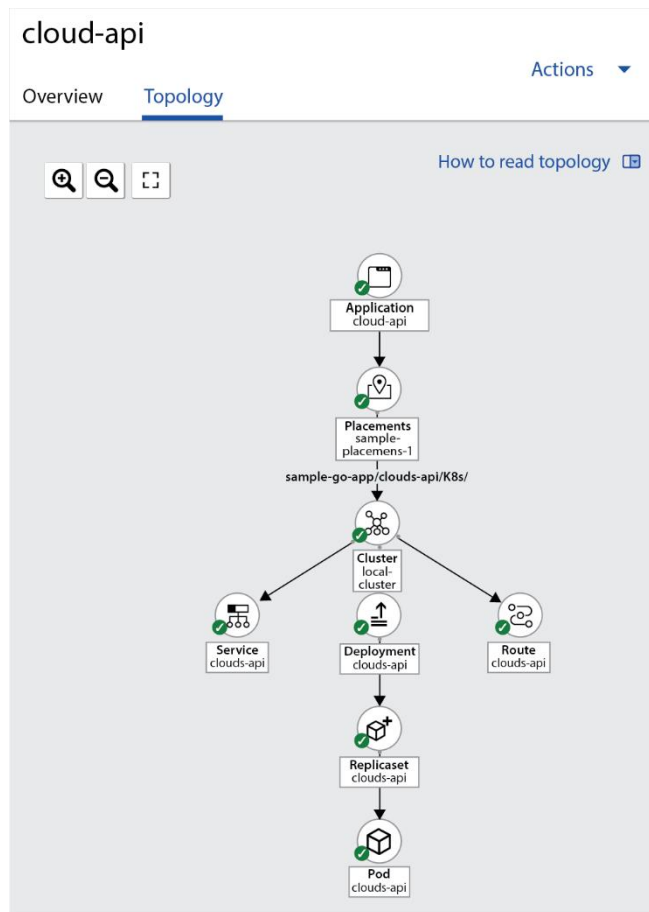

### Select resources to toggle their assignments to the cluster set

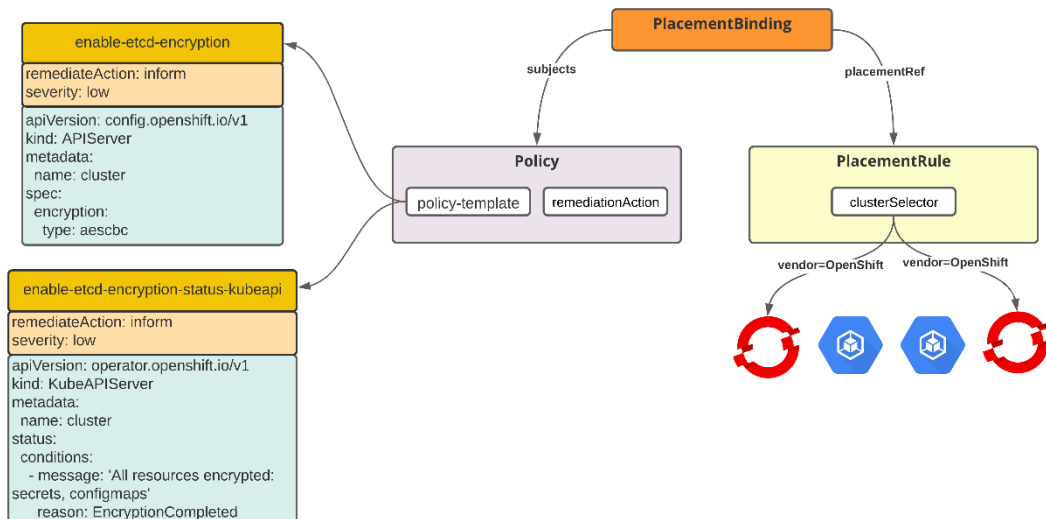

Resources can be added, removed, and transferred from other cluster sets (if you have permissions to remove from them from their assigned set).

**Important:** assigning a resource to the cluster set will give all cluster set users permissions to the resource's namespace.

## Why use Red Hat Advanced Cluster Security for Kubernetes?

Protecting cloud-native applications requires significant changes in how we approach security—we must apply controls earlier in the application development life cycle, use the infrastructure itself to apply controls, and keep up with increasingly rapid release schedules.

Red Hat® Advanced Cluster Security for Kubernetes, powered by StackRox technology, protects your vital applications across build, deploy, and runtime. Our software deploys in your infrastructure and integrates with your DevOps tooling and workflows to deliver better security and compliance. The policy engine includes hundreds of built-in controls to enforce DevOps and security best practices, industry standards such as CIS Benchmarks and National Institute of Standards Technology (NIST) guidelines, configuration management of both containers and Kubernetes, and runtime security.

Red Hat Advanced Cluster Security for Kubernetes provides a Kubernetes-native architecture for container security, enabling DevOps and InfoSec teams to operationalize security.

## Features and Benefits

### Kubernetes-native security:

1. Increases protection.
2. Eliminates blind spots, providing staff with insights into critical vulnerabilities and threat vectors.
3. Reduces time and costs.
4. Reduces the time and effort needed to implement security and streamlines security analysis, investigation, and remediation using the rich context Kubernetes provides.
5. Increases scalability and portability.
6. Provides scalability and resiliency native to Kubernetes, avoiding operational conflict and complexity that can result from out-of-band security controls.

## Using the RHACS Operator

### RHACS comes with two custom resources:

1. **Central Services** - Central is a deployment required on only one cluster in your environment. Users interact with RHACS via the user interface or APIs on Central. Central also sends notifications for

## Install Operator

Install your Operator by subscribing to one of the update channels to keep the Operator up to date. The strategy determines either manual or automatic updates.

**Note:** Some fields may not be represented in this form view. Please select "YAML view" for full control.

**Name \***stackrox-secured-cluster-services **Labels**

app=frontend

**Cluster Name \***

local-cluster

The unique name of this cluster, as it will be shown in the Red Hat Advanced Cluster Security UI.  
Note: Once a name is set here, you will not be able to change it again. You will need to delete and re-create this object in order to register a cluster with a new name.

**Central Endpoint**

central-rhacs-operator.apps. [REDACTED] m:443

The endpoint of the Red Hat Advanced Cluster Security Central instance to connect to, including the port number. If using a non-gRPC capable load balancer, use the WebSocket protocol by prefixing the endpoint address with wss://. Note: when leaving this blank, Sensor will attempt to connect to a Central instance running in the same namespace.

The screenshot shows the Red Hat Advanced Cluster Security for Kubernetes dashboard. On the left sidebar, the 'Platform Configuration' menu item is highlighted with a red box. The main content area displays the 'Policies' page, which includes a table of existing security policies. A red arrow points from the text 'Existing Security Policies' to the 'Policy' column header in the table.

Policy	Description	Status	Notifiers	Severity	Lifecycle
30-Day Scan Age	Alert on deployments with images that...	Enabled	-	Medium	Deploy
90-Day Image Age	Alert on deployments with images that...	Enabled	-	Low	Build, Deploy
ADD Command used instead of COPY	Alert on deployments using a ADD co...	Disabled	-	Low	Build, Deploy
Alpine Linux Package Manager (apk) in Image	Alert on deployments with the Alpine L...	Enabled	-	Low	Build, Deploy
Alpine Linux Package Manager Execution	Alert when the Alpine Linux package ...	Enabled	-	Low	Runtime

Severity	Medium
Categories	Anomalous Activity, Kubernetes Events
Type	System default
Description	Alert when the RHACS Central secret is accessed.
Rationale	The Central secret can be used to login to the Central user interface as the admin user. This secret is generally salted and hashed by default in the data.htpasswd field, but may contain a base64 encoded password in the field data.password (if deployed with an Operator). This field may be safely removed. This secret should only be accessed for break glass troubleshooting and initial configuration. An update or access of this secret may indicate that it will be used to administer and configure security controls.
Guidance	Ensure that the Central admin secret was accessed for valid business purposes.

---

## MITRE ATT&CK

➤ **Credential Access** [TA0006](#) 

The adversary is trying to steal account names and passwords. Credential Access consists of techniques for stealing credentials like account names and passwords. Techniques used to get credentials include keylogging or credential dumping. Using legitimate credentials can give adversaries access to systems, make them harder to detect, and provide the opportunity to create more accounts to help achieve their goals.

Description

The Red Hat Quay Operator deploys and manages a production-ready Red Hat Quay private container registry. This operator provides an opinionated installation and configuration of Red Hat Quay. All components required, including Clair, database, and storage, are provided in an operator-managed fashion. Each component may optionally be self-managed.

Operator Features

- Automated installation of Red Hat Quay
- Provisions instance of Redis
- Provisions PostgreSQL to support both Quay and Clair
- Installation of Clair for container scanning and integration with Quay
- Provisions and configures RHODCS for supported registry object storage
- Enables and configures Quay's registry mirroring feature

The screenshot shows the Red Hat OpenShift console interface. The top navigation bar includes the Red Hat logo, the user name 'kube-admin', and notification icons. A blue banner at the top states: "You are logged in as a temporary administrative user. Update the cluster OAuth configuration to allow others to log in".

The left sidebar contains various menu items: Pods, Deployments, DeploymentConfigs, StatefulSets, **Secrets**, ConfigMaps, CronJobs, Jobs, DaemonSets, ReplicaSets, ReplicationControllers, HorizontalPodAutoscalers, Networking, Storage, Builds, Observe, Compute, User Management, and Administration.

The main content area displays a table of secrets for the selected project, 'openshift-operators'. The table has columns for Name, Type, Data Size, Creation Time, and Actions. One row is highlighted with a red border:

At the bottom of the console, there is a terminal window showing the command: `console.openshift.com/console/apps/vspdf/gzu/captus/analytics/k8s/mroperishift/operators/deployments`.

The screenshot displays the Red Hat OpenShift console interface. On the left is a navigation sidebar with categories like Pods, Deployments, ConfigMaps, and Secrets. The 'Secrets' section is selected. The main panel shows the details for a specific secret: 'enterprise-registry-quay-config-editor-credentials-6dcm56t9'. It is an 'Opaque' type secret in the 'openshift-operators' namespace. A red rectangular box highlights the 'Data' section at the bottom, which contains two entries: 'password' and 'username'. Both values are masked with dots. A 'Reveal values' link is visible next to the 'password' entry.

Custom SSL Certificates

This section lists any custom or self-signed SSL certificates that are installed in the Quay container on startup after being read from the `extra_ca_certs` directory.

Custom certificates are typically used in place of publicly signed certificates for corporate-internal services.

Please **make sure** that all custom names used for downstream services (such as Clair) are listed in the certificates below.

Upload certificates:

Select file

Select custom certificate to add to configuration. Must be in PEM format and end extension '.crt'

CERTIFICATE FILENAME	STATUS
No custom certificates found.

Database Name: enterprise-registry-quay-database

SSL Certificate: [Eschobar archive](#) | [Nerihum archive](#) | [esochido](#)  
Optional SSL certificate (in PEM format) to use to connect to the database

#### Data Consistency Settings

Relax constraints on consistency guarantees for specific operations to enable higher performance and availability.

☐ Allow repository pulls even if audit logging fails.

If enabled, failures to write to the audit log will fallback from the database to the standard logger for registry pulls.

#### Time Machine

Time machine keeps older copies of tags within a repository for the configured period of time, after which they are garbage collected. This allows users to revert tags to older images in case they accidentally pushed a broken image. It is highly recommended to have time machine enabled, but it does take a bit more space in storage.

Allowed expiration periods:

- 4w [Remove](#)
- 2w [Remove](#)

[Add](#)

The expiration periods allowed for configuration. The default tag expiration "none" lies in this list.

Default expiration period: 2w

The default tag expiration period for all namespaces (users and organizations). Must be expressed in a duration string form: 30s, 1h, 1d, 2w.

Allow users to select expiration: ☒ Enable Expiration Configuration

If enabled, users will be able to select the tag expiration duration for the namespace(s) they administrate, from the configured list of options.

#### Redis

☒ Validate Configuration Changes

## Validating configuration

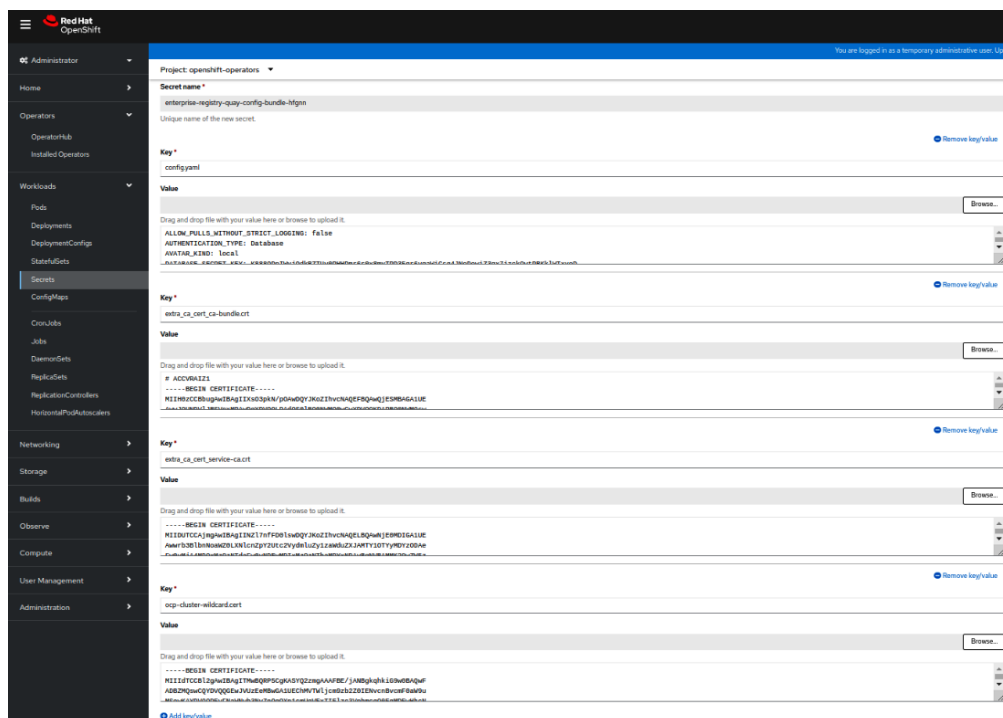

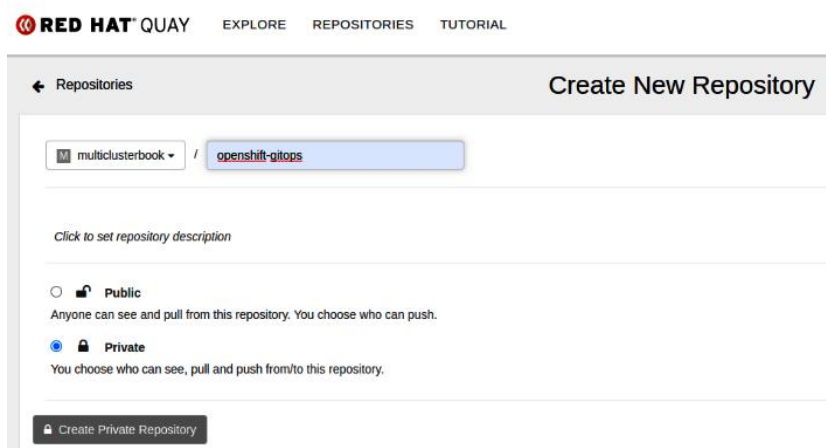

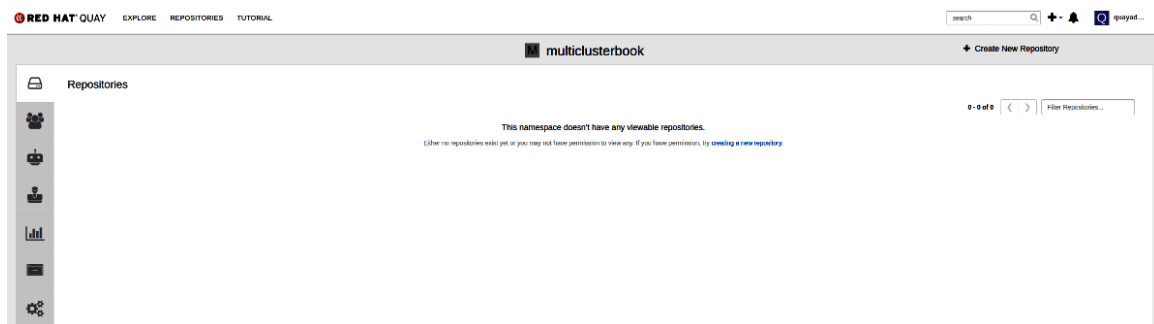

✓ Configuration Validated

[Continue Editing](#)

[Download](#)

[Reconfigure Quay](#)

## Step 2: Create a new container

The first step to creating an image is to create a container and fill it with some data.

First we'll create a container with a single new file based off of the `busybox` base image:

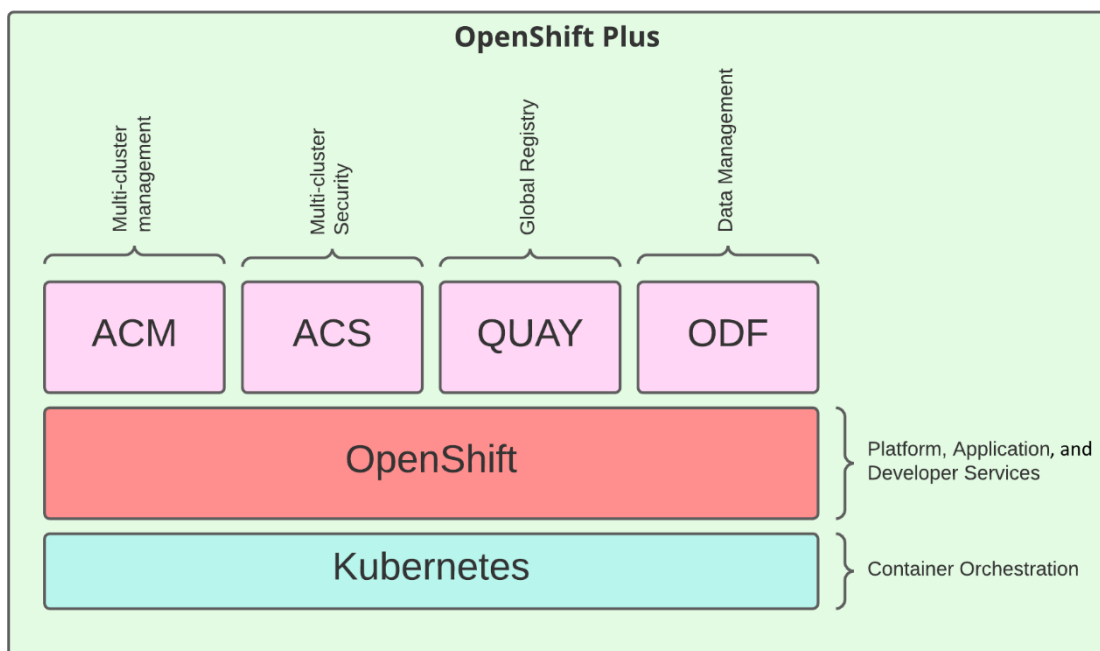

```
>_ docker run busybox echo "fun" > newfile
```

The container will immediately terminate (because its one command is `echo`), so we'll use `docker ps -l` to list it:

```
>_ docker ps -l
CONTAINER ID      IMAGE      COMMAND      CREATED
07f2065197ef     busybox:latest    echo fun     31 seconds ago
```

Enter the container ID returned:

## Credentials for demo+ocp

### Step 1: Download secret

First, download the [Kubernetes pull secret](#) for the robot account:

 [Download demo-ocp-secret.yml](#) </> [View demo-ocp-secret.yml](#)

### Step 2: Submit

Second, submit the secret to the cluster using this command:

```
kubectl create -f demo-ocp-secret.yml --namespace=NAMESPACEHERE
```

### Step 3: Update Kubernetes configuration

Finally, [add a reference to the secret to your Kubernetes pod config](#) via an `imagePullSecrets` field. For example:

```
apiVersion: v1
kind: Pod
metadata:
  name: somepod
  namespace: all
spec:
  containers:
    - name: web
      image: quay-registry-quay-openshift-operators.apps.ocp-22.sandbox735.opentlc.com/demo-ocp-secret
  imagePullSecrets:
    - name: demo-ocp-pull-secret
```
